Steve Shore - (Univ. Of Pisa)

Crystal Brogan – (Hawaii)

Glast Symposium Sept 2005

Outline

- I. Describe magnetic structures in the GC
- II. New interpretation based on low frequency wide-field imaging at 330 & 74 MHz
- III. What is the GC cosmic-ray energy density?

Glast Symposium Sept 2005

RIPA PPOL 4885 000 MHZ

6 cm VLA Image of G359.54 (Yusef-Zadeh et al 1997)

INNAME= A4 8/EC+CD PPOL 1

2-9 keV Chandra Image - Lu, Wang & Lang 2003

Glast Symposium Sept 2005

Observed Characteristics

- Extreme length to width ratios (10-100)
- Highly polarized (30-70%)
- Strong (1 mG) magnetic fields aligned along their long axis
- Subfilamentation & braiding
- Associated with molecular clouds
- Peak intensity located near the geometric center
- Nonthermal spectra with curvature above 5 GHz

Questions theory must address

- Are the NTFs Global or local magnetic fields? Static or dynamic?
- What is the acceleration mechanism? Is it local or is the acceleration distributed along the length of the NTF?
- Why are they only observed at the Galactic Center?

Pervasive Field Model

- Magnetic pressure exceeds the thermal pressure, therefore unless confined the filaments would expand on a timescale short compared to their synchrotron lifetime
- Filaments are locally illuminated flux tubes of a space-filling, globally organized field
- Magnetic field energy required – 10^{54-55} ergs

Summary of Known & Probable NTFs

- 10 confirmed NTFs perpendicular to the galactic plane
 - 2 confirmed NTFs non perpendicular
 - Several sources show NTF morphology with a variety of orientations to the galactic plane and other NTFs
- ⇒ more complex magnetic field geometry

Simulation of a cloud moving transverse to
magnetic field – Gregori et al 2000

Glast Symposium Sept 2005

2-D Simulation of a Wake

- Initialized with small perturbations to insure unstable modes are naturally excited
- A linear code determines the fastest growing wavelength (KH instability) to normalize the scales for the full nonlinear calculation
- Exterior wind is 2000 km/s, $n_{\infty}=1 \text{ cm}^{-3}$, $B_{\infty}=10^{-2} \text{ mG}$, interior field 1 mG

FIG. 6.—Filled contour plots of $|B|^2$. The gray scale is linear with white maximum and black minimum. The maximum amplification relative to the peak in Fig. 1 is about a factor of 3 in field strength. The times for each snapshot are 190, 220, 250, and 280 growth times corresponding to about 5, 20, 40, and 60 distance units (see text).

Energy Requirements

- Total energy = $(\phi^{4/7} f^{3/7}) \times 10^{52}$ ergs

$$\text{Particle energy} = 1 (\phi f)^{2/7} \text{ eV/cm}^3$$

- $B \approx 6 (\phi f)^{2/7} \mu\text{G} \Rightarrow \text{lifetime } 5 \times 10^7 \text{ yrs}$
 $\Rightarrow 200 \text{ Sne over this lifetime, or 1 every } 10^5 \text{ yrs}$
- Consistent with soft x-ray measurements

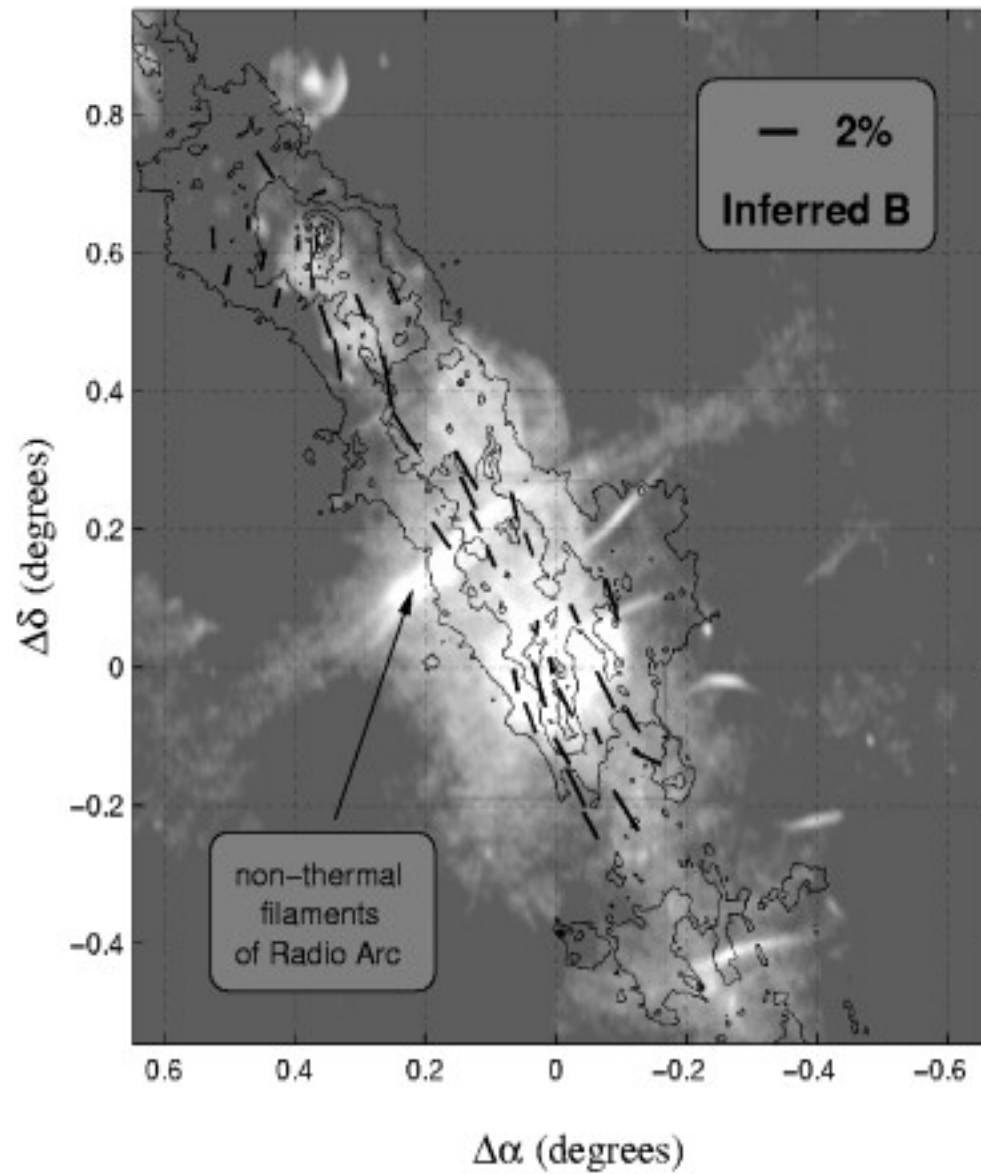

What is the GC cosmic-ray energy density

- For just the inner 1.5 degrees the minimum energy analysis indicates $B \approx 11 \mu\text{G}$ with a corresponding electron energy density of 7 eV/cm^3
- Local ISM is 0.2 eV/cm^3
- If $B \approx 1 \text{ mG}$ observed intensity $\Rightarrow 0.04 \text{ eV/cm}^3$
- Is the diffuse γ -ray emission consistent with either of these numbers?

What is the GC cosmic-ray energy density

- Gamma-ray observations (EGRET) indicate a cosmic ray energy density similar to the disk
- Ionization rate derived from H_3^+ is very high $\xi = 2\text{--}7 \times 10^{-15} \text{ s}^{-1} \text{ cm}^{-3}$ (Oka et al 2005)
- Searches for spallation products Li & B suggest upper limits of ≈ 10 times local ISM (Lubowich et al 1998)

Novak et al
2003

Glast Symposium Sept 2005

Figure 5. The plot of the RM towards various sources as a function of the Galactic longitude and latitude. The cross symbol (x) indicates positive RM and the circle (O) negative RMs, where the symbol size increases linearly with $|\text{RM}|$.

Conclusions:

- Confirmed population of NTFs is difficult to reconcile with a globally ordered field
 \Rightarrow *complex field geometry*
- NTFs could be generated by dynamically
 \Rightarrow *strong pervasive field not required*
- Low frequency, diffuse nonthermal emission
 \Rightarrow *weak global magnetic field*
- Cosmic-ray energy density needed

Glast Symposium Sept 2005

Fig. 4. A BGF map same as figure 1 but at 2.7 GHz from the Bonn survey (Reich et al. 1984). The HPBW of the map is 4/3. A BGF has been applied with the same filtering beam size of 1'0 as in figure 1. The unit of the contour numbers is $10^{-21} \text{ W m}^{-2} \text{ sr}^{-1} \text{ Hz}^{-1}$.
